01 / THE PROJECT

A calmer desk for a busy kitchen.

Orderly turns a pasted customer message into a reviewed bakery order and a combined preparation list. It is a small, functioning browser app built for an easy-to-understand demonstration.

Problem hypothesis

Independent bakers may spend time copying quantities, dates and prices from chats into a notebook or spreadsheet. Amendments and incomplete messages may introduce errors. These are hypotheses for customer interviews, not verified research findings.

First customer to test with

An independent home baker who personally handles chat orders and kitchen planning. The pilot should use anonymized orders and the baker's real menu, with permission.

What is working	Current boundary
Message parsing, review form, price totals	English text and known menu products
Order book and kitchen preparation list	One browser profile; no shared cloud database
Reply draft, CSV and JSON backup	Manual copy/send; no messaging or payments
Configurable menu and prices	Per-piece INR prices; fees and taxes separate

Product claim: a working prototype ready for customer testing. It uses deterministic local text rules, not a language model. No customer traction or time savings are claimed.

02 / THE DEMONSTRATION

One message becomes a checked order.

Fictional message: “Hi, I'm Ananya. Can I get 6 choco chip cookies and 4 brownies for tomorrow at 5 pm? Pickup please.”

With the message date set to 10 October 2026, the parser returns 11 October 2026, 17:00, Pickup. The reference date is editable so an older message does not silently use today.

Menu item	Quantity	Unit price	Amount
Choco chip cookie	6	INR 65	INR 390
Brownie	4	INR 90	INR 360
Items total			INR 750

The review is part of the workflow

The user checks the extracted details, fills gaps, confirms the review checkbox and saves. The saved order contains a snapshot of the item prices. Updating the menu does not rewrite earlier orders.

A request such as “a box of brownies” leaves the piece quantity blank. Repeated products, changed wording and dietary requests trigger checks. The parser can still miss unusual language, so every draft needs manual review.

Kitchen preparation

The preparation list groups active orders by date and product. Ready orders remain visible until completed, while the “to bake” column excludes ready quantities. Completed orders leave the active preparation list.

03 / IMPLEMENTATION AND CHECKS

Simple enough to explain. Useful enough to test.

The application uses buildless HTML, CSS and JavaScript modules. The pure order logic is separate from the interface. Browser localStorage holds the menu and saved orders. CSV and JSON exports provide a portable copy.

Check area	Observed result
Menu quantities and price arithmetic	6 cookies + 4 brownies = INR 750
Incomplete and revised requests	Missing quantities and changes are flagged
Dates and fulfilment	Invalid days rejected; delivery requires an address
Preparation aggregation	Completed excluded; ready counted separately
CSV and price snapshots	Formula-like input escaped; earlier prices retained
Automated core test suite	14 checks passed
Optional n8n workflow code	Embedded JavaScript executed locally; expected output verified

What the checks do not establish

Full browser interaction and screenshot QA were unavailable in this session. The n8n JSON has not been imported into a live n8n instance. Customer usability, parsing accuracy on real messages, dietary suitability and business impact remain unverified.

Privacy and operating limits

Message content stays in the browser application. The host serves the page and may handle normal access logs. A shared browser profile can access its local records. Clearing browser data removes records unless backed up. Saved order content currently requires deletion and recreation to correct.

04 / VALIDATION PLAN

A prototype is the start of the evidence.

Evidence	Actual status	Target / next step
Customer interviews	0 verified	20+ interviews from the roadmap
Pilot commitments	0 signed	5 actual pilot commitments
Wait-list	No verified signups	25 by Day 10
Customer time savings	Not measured	Paired baseline and tool timing
Customer outreach	Not performed	Share evidence-backed material with prospects

The 14-day sequence

Days 0-2: define the customer, build a discovery pipeline, interview and cluster pain points. Days 3-6: revise the MVP, measure the task and seek genuine pilot commitments. Days 7-10: publish a landing page and useful evidence, then test distribution. Days 11-14: run approved outreach, demonstrate to pilots, review results and present.

The supplied roadmap also requests a 49-page report/KDP link, 19 directory submissions, three community posts and a 100-email campaign. Those need real research, audience fit and authorized publication. Templates are included; these activities are not claimed as completed.

Measurement and decision gates

Time five anonymized orders per participant, include corrections, and compare median seconds to a correct result with the existing method. Track repeat use a week later. The source gates are fewer than 3 signed LOIs by Day 6 and fewer than 25 wait-list signups by Day 10. Do not replace missing outcomes with estimates.

Scheduling note: the source suggests about 3 hours daily, but 20 interviews of 15 minutes total 5 hours before notes. Spread calls across a team or allow extra time.

05 / SUBMISSION HANDOFF

Show the product. Keep the story honest.

Deliverable	Prepared result
Live project	Public Orderly browser app
Source / workflow	Complete source plus downloadable n8n workflow JSON
Demo	90-second captioned animated walkthrough, using actual engine output and fictional orders
Case study	This implementation record and validation plan
Pitch	Six sections: problem, solution, demo, traction, build journey, team
GTM materials	Interview guide, evidence logs, pilot-interest form, check-ins and execution plan

The video is an animated walkthrough, not a recording of browser interaction or a customer testimonial. Use the live app during the presentation, and keep the MP4 as an offline backup. If the evaluator requires screen capture, record the included script against the live app.

Submission links

The submission form accepts a GitHub repository or workflow JSON. Use the downloadable JSON for that field. The demo and this case study are hosted alongside the public application. Customer research and measured outcomes remain next steps.
